

Visualization 1: Evolution Over Time

The "Spaghetti" Line Chart with Highlighting (The Classic) :

The Design: The X-axis represents Time (1900–2020), and the Y-axis represents the absolute count or relative frequency. Each line is a name.

How it works: Because plotting all names would create an unreadable "spaghetti" mess, the chart starts mostly grayed out. The user can search/select specific names to highlight them in bold colors.

Why it fits: It is the most precise way to compare the exact peaks and valleys of a few selected names over time, making it easy to spot sudden spikes (like the famous "Kevin" spike in the early 90s).

Visualization 2: Regional Effects

Interactive Choropleth Map (The Geographic View)

The Design: A map of French departments. The user selects a specific Name and an Era/Year.

How it works: The map colors each department based on the per capita popularity of that name (to adjust for population density differences between Paris and rural areas).

Why it fits: It instantly answers "Are some names more popular in some regions?" by revealing distinct cultural clusters (e.g., Breton names in the northwest, Basque names in the southwest, or Corsican names).

Visualization 3: Gender Effects

Centered Butterfly Chart

The Design: The vertical axis in the center represents Time (grouped by decades or years). Bars extend to the left for Males and to the right for Females for a chosen name.

How it works: Symmetrical shapes mean consistent popularity across both sexes. Lopsided shapes show a gender skew.

Why it fits: It is an excellent way to see the total volume of a name alongside its gender proportion at a single glance.
